Webinar 1 (October 2024)

The screenshot shows the top navigation bar of the Cochrane Training website. On the left is the Cochrane Training logo with the tagline "Trusted evidence. Informed decisions. Better health." To the right is a search bar with a magnifying glass icon. Below the search bar is a purple navigation bar with links for "Online learning", "Learning events", "Guides and handbooks", "Trainers' Hub", and a "Log in" button.

Introduction to new random-effects methods in RevMan

There are many methods available to fit random-effects meta-analysis. However, until 2024, the only option available in RevMan has been the DerSimonian and Laird random-effects method. This method is known to have poor statistical performance in meta-analyses with characteristics commonly found in Cochrane reviews (e.g., meta-analyses with few studies). To address this issue, Cochrane is implementing new random-effects methods in RevMan. These include a new method for estimating the between-study (heterogeneity) variance, calculating the confidence interval for the summary effect, and adding prediction intervals to aid in interpreting random-effects meta-analysis findings.

The banner features a photograph of a woman smiling while working on a laptop. To the right of the photo, the text reads "Learning Live" in a purple box, followed by "Methods Support Unit web clinic" in a dark blue box. Below this, it says "A monthly web clinic for Cochrane authors, editors & staff" in a light blue box, and the Cochrane Methods logo is at the bottom right.

- Process used to develop the recommendations for the random-effects meta-analysis methods to be implemented in RevMan
- Outlined the new methods, along with the reasons for why the methods had been selected

Webinar 2: Objective

To demonstrate the new random-effects meta-analysis methods in RevMan

Outline

- Brief overview of the random-effects methods that are available in RevMan (as of the 23rd January 2025)
- Demonstration of the methods using RevMan (including what method to use in which scenario):
 - Confidence interval methods for the summary mean effect
 - Heterogeneity estimators (and confidence interval method)
 - Prediction interval
- Considerations for what to write in the protocol and review report
- Questions

Characteristics and
preparing for
synthesis

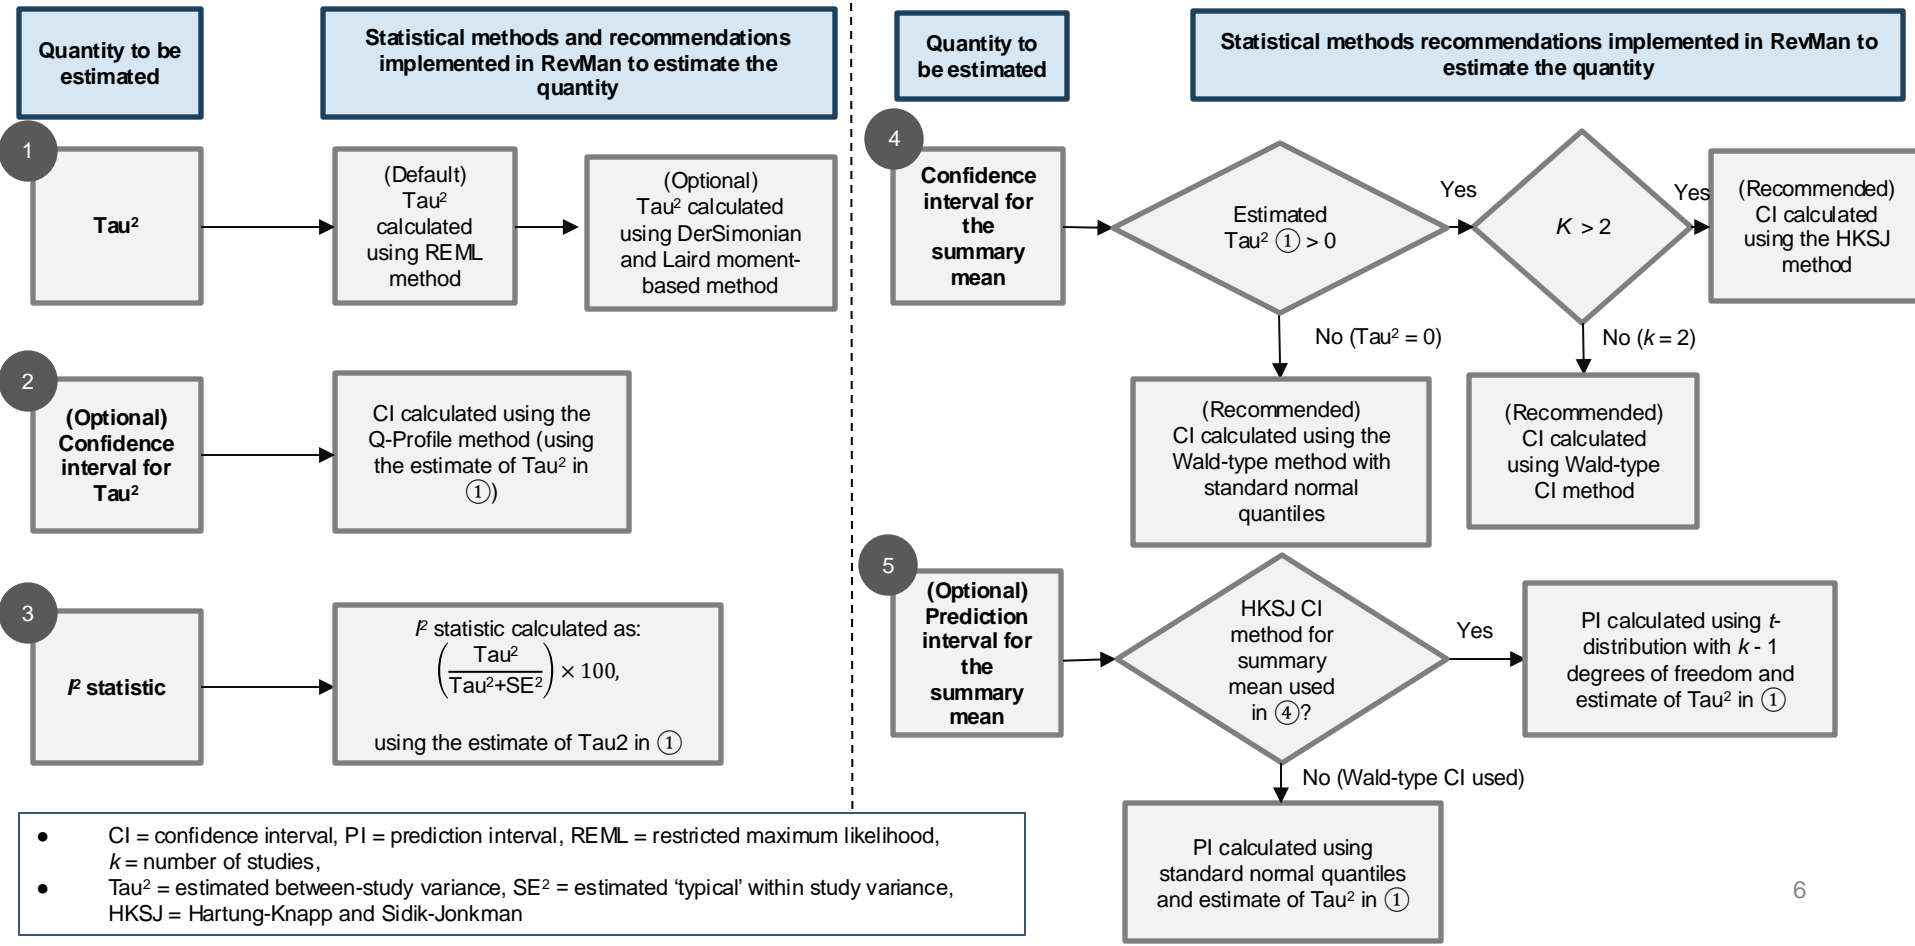

- ◆ Chapter 10: Analysing data and undertaking meta-analyses
- ◆ 10.1 Do not start here!
- ◆ 10.2 Introduction to meta-analysis
- ◆ 10.3 A generic inverse-variance approach to meta-

Jonathan J Deeks, Julian PT Higgins, Douglas G Altman, Joanne E McKenzie and Areti Angeliki Veroniki; on behalf of the Cochrane Statistical Methods Group

Key Points:

- Meta-analysis is the statistical combination of results from two or more separate studies.
- Potential advantages of meta-analyses include an improvement in precision, the ability to answer questions not posed by individual studies, and the opportunity to settle controversies arising from conflicting claims. However, they also have the potential to mislead seriously, particularly if specific study designs, within-study biases, variation across studies, and reporting biases are not carefully considered.
- It is important to be familiar with the type of data (e.g. dichotomous, continuous) that result from measurement of an outcome in an individual study, and to choose suitable effect measures for comparing intervention groups.

Fitting a random-effects meta-analysis in RevMan

Inference on heterogeneity (τ^2):

- We will show the option to fit a DerSimonian-Laird (DL) (*standard option*)
- Indicate and highlight the use of the Restricted Maximum Likelihood (REML) method (*recommended*)

Inference on summary mean effect (μ):

- We will show the option to fit a Wald Type (WT) confidence interval (CI) or μ (*standard option*)
- Indicate and highlight the use of the Hartung-Knapp-Sidik-Jonkman (HKSJ) CI (*recommended when $\tau^2 > 0$ and # of studies > 2*)

What was in RevMan up to now:

- DL and Wald Type (WT) methods

New methods:

- REML and HKSJ methods

| Heterogeneity: Tau ² (REML ^b , 95% CI) = 0.26 [0.00 , >100]; Chi ² = 1.98, df = 1 (P = 0.16); I ² = 49% | | | | | | | |

Footnotes

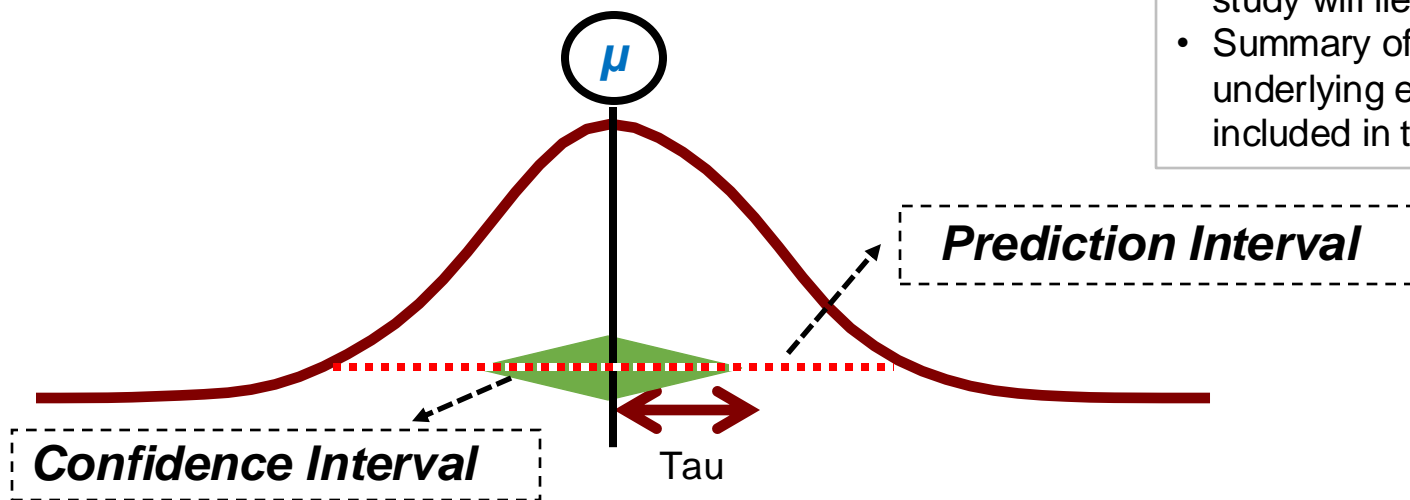

^aCI calculated by Wald-type method.

^bTau² calculated by Restricted Maximum-Likelihood method.

Prediction Intervals for random-effects meta-analysis

A 95% prediction interval where approximately 95% of the true treatment effects are predicted to fall is:

$$\hat{\mu} \pm 1.96 \times Tau$$

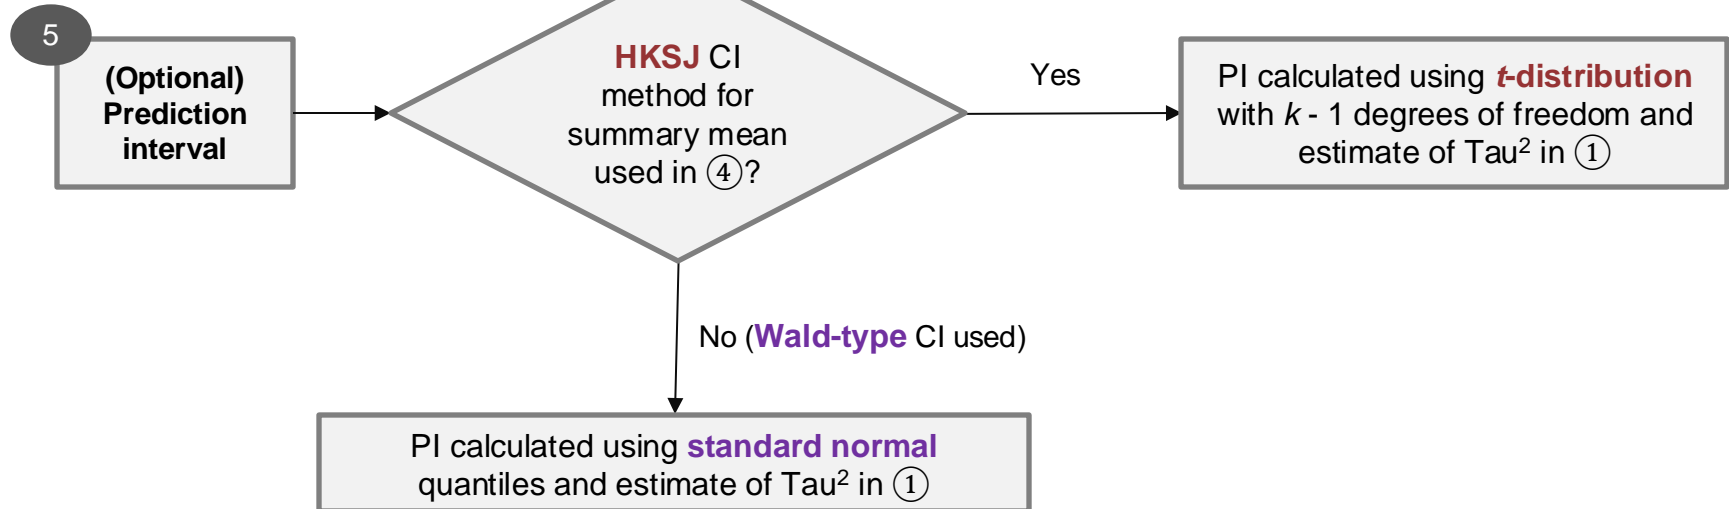

- The interval within which we expect that the effect of a future study will lie
- Summary of the spread of underlying effects in the studies included in the meta-analysis

Prediction intervals for random-effects meta-analysis

Quantity to be estimated

Statistical methods and decision rules implemented in RevMan to estimate the quantity

- CI = confidence interval, PI = prediction interval, REML = restricted maximum likelihood, k = number of studies,
- Tau^2 = estimated between-study variance, SE^2 = estimated 'typical' within study variance, HKSJ = Hartung-Knapp and Sidik-Jonkman

Prediction Interval

Random effects

i Heterogeneity estimator

- DerSimonian and Laird (DL)
 Restricted Maximum-Likelihood (REML)

Show confidence interval for heterogeneity estimator on forest plot **i**

Totals

Totals and subtotals

Test for subgroup differences

Swap event and non-event

Show prediction interval for total on forest plot **i**

Confidence / prediction intervals

95%

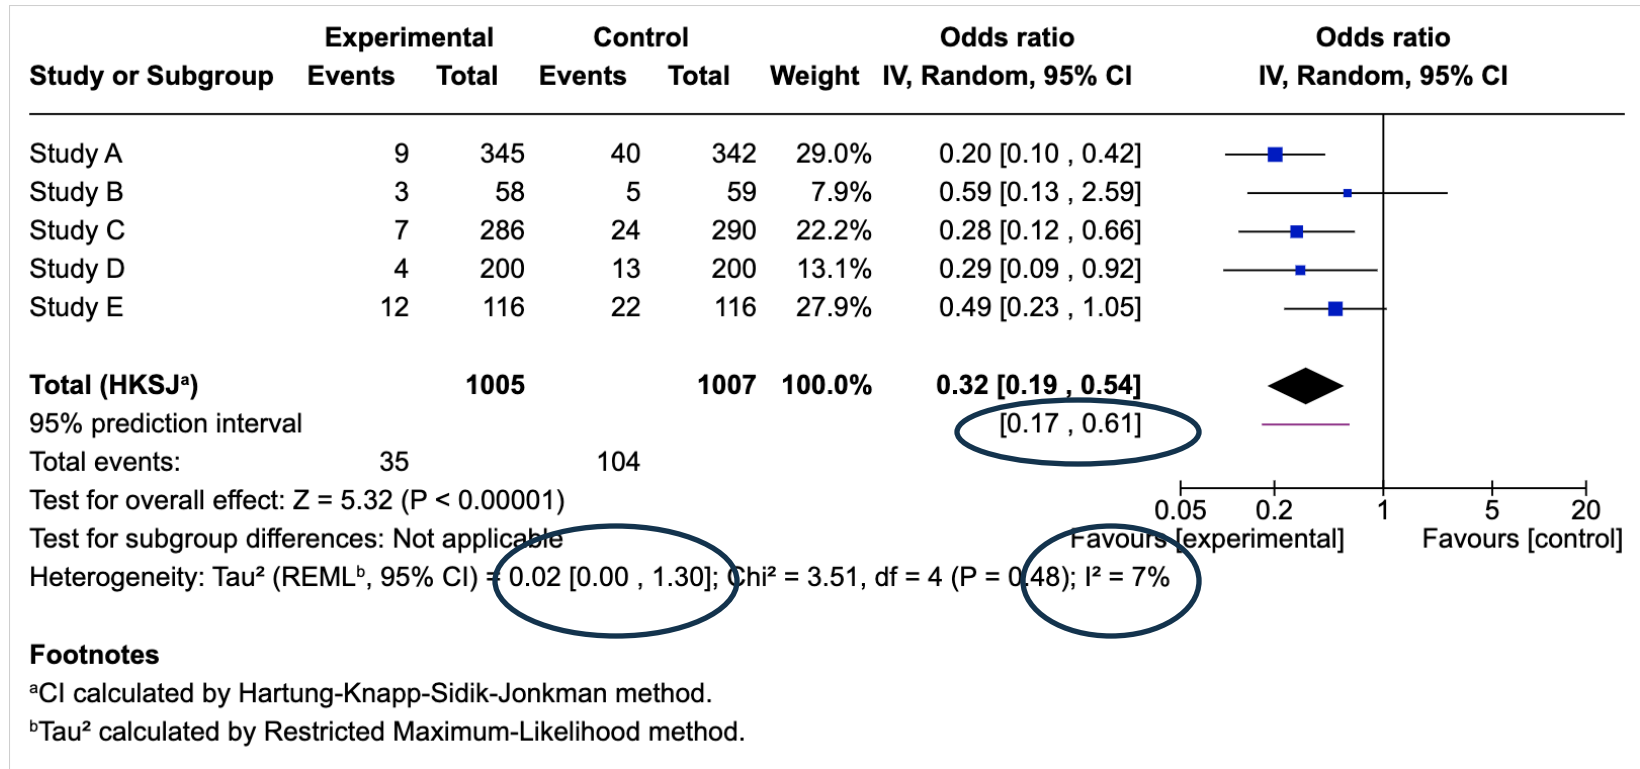

i Summary effect CI method

- Wald-type
 Hartung Knapp Sidik Jonkman (HKSJ)

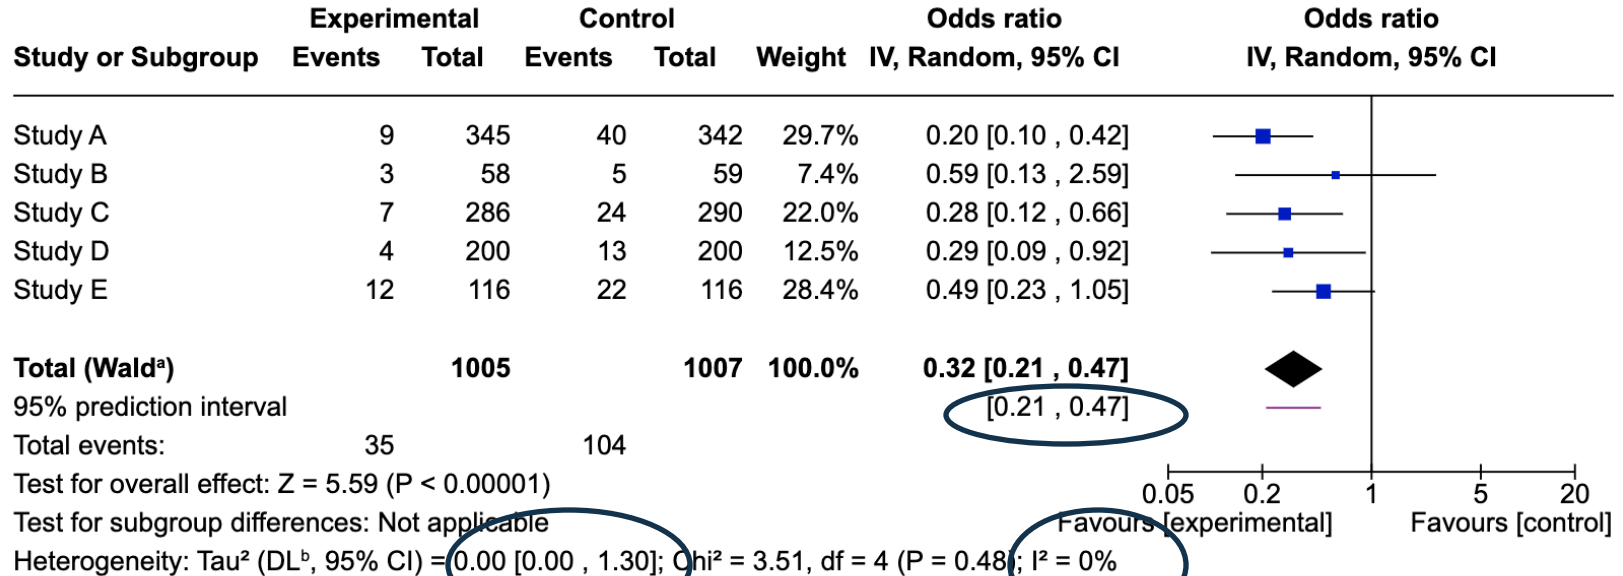

*Check box
to obtain a
PI*

Prediction Interval

PI is equal to CI when $\tau^2=0$

PI is different between WT and HKSJ, as it is based on the standard normal and t-distribution, respectively

^aCI calculated by Wald-type method.

^bTau² calculated by DerSimonian and Laird method.

Considerations for what to write in the protocol and review report

- Be aware of the random-effects methods and the recommendations for what method to use in which scenario when planning the statistical methods in your review → see Chapter 10 of the Cochrane Handbook
- PRISMA 2020 helpful for guiding what to report

PRISMA 2020 – item 13d

Describe any methods used to synthesise results and provide a rationale for the choice(s). If meta-analysis was performed, **describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used**

Essential elements (some):

If meta-analysis was done, specify:

- the meta-analysis model (fixed-effect, fixed effects, or random-effects) and provide rationale for the selected model
- the method used (such as Mantel-Haenszel, inverse-variance)
- any methods used to identify or quantify statistical heterogeneity (such as visual inspection of results, a formal statistical test for heterogeneity, heterogeneity variance (τ^2), inconsistency (such as I^2), and prediction intervals)

PRISMA 2020 – item 13d (continued)

Describe any methods used to synthesise results and provide a rationale for the choice(s). If meta-analysis was performed, **describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used**

Essential elements (some):

If a random-effects meta-analysis model was used, specify:

- the between-study (heterogeneity) variance estimator used (such as DerSimonian and Laird, restricted maximum likelihood (REML))
- the method used to calculate the confidence interval for the summary effect (such as Wald-type confidence interval, Hartung-Knapp-Sidik-Jonkman)

An example (protocol)

“We will combine estimates of treatment effect using inverse variance weighting, using a random-effects model. We will use a random-effects model since we expect there will be clinical diversity in ... The Restricted Maximum Likelihood (REML) method will be used to estimate between-trial variance, and a confidence interval will for the heterogeneity estimate will be calculated. The Hartung-Knapp-Sidik-Jonkman method will be used to calculate a confidence interval for the meta-analysis effect estimate when there are at least 3 studies and the estimate of heterogeneity is greater than zero. In other scenarios (i.e. 2 studies, or where the estimate of heterogeneity is equal to zero) we will use the Wald-type method. We will calculate prediction intervals to provide a predicted range for the true treatment effect in an individual study.”

An example (protocol)

“We will combine estimates of treatment effect using inverse variance weighting, using a random-effects model. We will use a random-effects model since we expect there will be clinical diversity in ... The **Restricted Maximum Likelihood (REML) method will be used to estimate between-trial variance**, and a confidence interval will for the heterogeneity estimate will be calculated. The Hartung-Knapp-Sidik-Jonkman method will be used to calculate a confidence interval for the meta-analysis effect estimate when there are at least 3 studies and the estimate of heterogeneity is greater than zero. In other scenarios (i.e. 2 studies, or where the estimate of heterogeneity is equal to zero) we will use the Wald-type method. We will calculate prediction intervals to provide a predicted range for the true treatment effect in an individual study when there are at least 10 studies.”

Method used to calculate the between-study (heterogeneity) variance (τ^2)

An example (protocol)

“We will combine estimates of treatment effect using inverse variance weighting, using a random-effects model. We will use a random-effects model since we expect there will be clinical diversity in ... The Restricted Maximum Likelihood (REML) method will be used to estimate between-trial variance, and **a confidence interval will for the heterogeneity estimate will be calculated**. The Hartung-Knapp-Sidik-Jonkman method will be used to calculate a confidence interval for the meta-analysis effect estimate when there are at least 3 studies and the estimate of heterogeneity is greater than zero. In other scenarios (i.e. 2 studies, or where the estimate of heterogeneity is equal to zero) we will use the Wald-type method. We will calculate prediction intervals to provide a predicted range for the true treatment effect in an individual study when there are at least 10 studies.”

A confidence interval for τ^2 will be calculated (note that the specific method has not been described)

An example (protocol)

“We will combine estimates of treatment effect using inverse variance weighting, using a random-effects model. We will use a random-effects model since we expect there will be clinical diversity in ... The Restricted Maximum Likelihood (REML) estimator will be used to estimate between-trial variance, and a confidence interval will for the heterogeneity estimate will be calculated. **The Hartung-Knapp-Sidik-Jonkman method will be used to calculate a confidence interval for the meta-analysis effect estimate when there are at least 3 studies and the estimate of heterogeneity is greater than zero. In other scenarios (i.e. 2 studies, or where the estimate of heterogeneity is equal to zero) we will use the Wald-type method.** We will calculate prediction intervals to provide a predicted range for the true treatment effect in an individual study when there are at least 10 studies.”

Decision rules to determine what confidence interval method for the summary mean will be used in which scenario

An example (protocol)

“We will combine estimates of treatment effect using inverse variance weighting, using a random-effects model. We will use a random-effects model since we expect there will be clinical diversity in ... The Restricted Maximum Likelihood (REML) estimator will be used to estimate between-trial variance, and a confidence interval will for the heterogeneity estimate will be calculated. The Hartung-Knapp-Sidik-Jonkman method will be used to calculate a confidence interval for the meta-analysis effect estimate when there are at least 3 studies and the estimate of heterogeneity is greater than zero. In other scenarios (i.e. 2 studies, or where the estimate of heterogeneity is equal to zero) we will use the Wald-type method. **We will calculate prediction intervals to provide a predicted range for the true treatment effect in an individual study when there are at least 10 studies.**”

A prediction interval will be calculated, along with the scenario when it will be calculated

Be sure to avoid ...

- Fitting multiple meta-analysis methods and reporting the results that are most favourable
